*Echinococcus multilocularis* was not detected in any of the 625 red foxes (*Vulpes vulpes*) examined during the 2012-2013 licensed hunting season.

**Introduction**

*Echinococcus multilocularis* is endemic in large parts of the northern hemisphere, including eastern and central parts of Europe (1, 2). In 1999, *E. multilocularis* was detected in Denmark (3) and on the high-arctic Norwegian islands of Svalbard (4). There was no evidence that this parasite had established in mainland Fennoscandia (5) prior to its detection in Sweden in February 2011 (6).

*E. multilocularis* has yet to be detected in mainland Norway, and anthelmintic treatment of dogs, prior to import, is compulsory to prevent introduction of the parasite from endemic EU regions. However, according to the EU Directive 998/2003/EC on pet movement, the maintenance of this national regulation post 2008 requires documentation of an *E. multilocularis* - free status within Norway.

**Aim**

The aim of the programme is to document freedom of *E. multilocularis* in mainland Norway.

**Material and methods**

Faecal samples collected from red foxes shot during the 2012-2013 licensed hunting season (from mid-July 2012 to April 2013) were included in this year’s program. All regions of Norway were represented in the sampling regime. Hunters were invited to participate based on a list of registered fox hunters. A standard form that included information on where and when the fox had been hunted, as well as the sex (male or female) and presumed age of the animal (juvenile or adult), was completed by each hunter.

The method used for the detection of *Echinococcus multilocularis* in the faecal samples was the newly developed DNA-fishing technique. This involves targeted DNA extraction from samples by applying specific DNA-hybridisation, followed by isolation using streptavidin coated magnetic beads (Mats Isaksson, National Veterinary Institute, personal communication) and finally detection using a realtime PCR (7). The new method is also capable of detecting DNA from adult worms, in addition to eggs. These methods are targeted for use during the patent phase of the intestinal infection, more precisely when DNA from the eggs will be shed in the faeces. This period constitutes roughly two-thirds of the total infection period. The combination of the new methods were shown to be more sensitive than the previously used method; egg isolation using physical sieving followed by detection of parasite DNA using a multiplex PCR (8).

A total of 625 samples were run individually (3 g faeces examined per sample). We assumed a fox population of 70,000 (Olav Hjeljord, Norwegian University of Life Sciences, personal communication), a test sensitivity of 63% (7) for the last two hunting seasons, and a sensitivity of 30% for the preceding hunting seasons to account for the lower sensitivity of the test used until 2011. The apparent prevalence and corresponding confidence interval were estimated using the function epi.prev in package epiR performed in R version 2.6.2 (9). We used the average sensitivity for the tests used during 2009-2013 (30% sensitivity for 2009-2011 and 63% sensitivity for 2012-2013, i.e. 46% sensitivity for the whole period) when calculating the apparent prevalence for the last five years.
Results
A total of 656 fox samples were collected during the 2012-2013 hunting season, of which 625 were suitable for examination (Figure 1). All samples were negative for *E. multilocularis* giving an estimated apparent prevalence of 0% (0 - 0.6%, 95% confidence interval). During the last five hunting seasons (from 2008-2009 to 2012-2013) a total of 2168 foxes have been examined. All foxes have tested negative giving an estimated prevalence of 0% (0 - 0.2%). In total, 3405 red fox faecal samples, from mainland Norway, have been tested for *E. multilocularis* between 2002 and 2013 (Table 1).

Discussion
The 2012/2013 result is in agreement with the results from previous years with no positive samples detected. The cumulative sample size during the last five years is sufficient to confirm that the prevalence is less than 1%. This means that Norway fulfils the criteria, as given by EFSA (10), to document that *E. multilocularis* infection is absent from the national fox population. However, the criteria set by EFSA allow for samples to be collected over a five year period without taking into account the probability of introduction during the same period. Wahlström et al (5) showed that, even when taking into consideration the probability of introduction of infection, the number of samples collected until 2009 in Norway was sufficient to document that the prevalence was lower than 1%.

The detection of *E. multilocularis* in Sweden in 2011 and recently also in a new region in Denmark (11) have increased the risk of introduction of the parasite to Norway. As a consequence, an annual surveillance programme is necessary to document a continuous disease free status. Our findings support the maintenance of the national regulation for compulsory anthelmintic treatment of imported dogs to minimise the risk of *E. multilocularis* introduction to Norway.

The Norwegian Veterinary Institute (NVI) is a nationwide research institute in the fields of animal health, fish health, and food safety. The primary mission of the NVI is to give research-based independent advisory support to ministries and governing authorities. Preparedness, diagnostics, surveillance, reference functions, risk assessments, and advisory and educational functions are the most important areas of operation.

The Norwegian Veterinary Institute has its main laboratory in Oslo, with regional laboratories in Sandnes, Bergen, Trondheim, Harstad og Tromsø, with about 360 employees in total.

The Norwegian Food Safety Authority (NFSA) is a governmental body whose aim is to ensure through regulations and controls that food and drinking water are as safe and healthy as possible for consumers and to promote plant, fish and animal health and ethical farming of fish and animals. We encourage environmentally friendly production and we also regulate and control cosmetics, veterinary medicines and animal health personnel. The NFSA drafts and provides information on legislation, performs risk-based inspections, monitors food safety, plant, fish and animal health, draws up contingency plans and provides updates on developments in our field of competence.

The NFSA comprises three administrative levels, and has some 1300 employees.

The NFSA advises and reports to the Ministry of Agriculture and Food, the Ministry of Fisheries and Coastal Affairs and the Ministry of Health and Care Services.
